

Answer Key — How Nature Works in Harmony

Final answers with brief reasons.

Objective

- Q1 (a) **habitat** — the living place is the habitat.
-
- Q2 (b) **water** — water is non-living — abiotic.
-
- Q3 (b) **population** — same-kind organisms form a population.
-
- Q4 (a) **biotic–biotic interaction** — both are living — biotic-biotic.
-
- Q5 (a) **connecting habitats for safe animal movement** — corridors link habitats, reducing conflict.
-
- Q6 (a) **True** — pollination is essential for seeds and fruits.
-
- Q7 **biotic** — living parts are biotic.
-
- Q8 **community** — they form a community.
-

Short answer

- Q9 Biotic = living (plants, animals); abiotic = non-living (water, soil, sunlight).
-
- Q10 A population is one kind of organism in a habitat; a community is all the different populations together.
-
- Q11 Habitat loss (forest shrinkage) leaves food/water scarce, so they enter farms; corridors connect forests so they can move safely without conflict.
-

Long / application

- Q12 Fish eat dragonfly larvae, so removing fish increases dragonflies. Dragonflies eat bees/butterflies, so more dragonflies means fewer pollinators, so fewer flowers are pollinated and fewer seeds form. Thus fish numbers indirectly affect plant seed production — showing interdependence.
-
- Q13 Cutting forests and changing land use shrink habitats; animals lose food and shelter and enter human areas, causing conflict and damage. Protection: conserve forests and create wildlife corridors connecting habitats so animals can move safely, keeping nature in balance.
